LABORATORY WORK №1

Student: Arzu Karimova

Subject: Programming Fundamentals / Python

GitHub Repository: LAB1 Repository

1. Aim of the Laboratory Work

The main goal of this lab is to practice basic Python programming. We learned how to write simple programs, get inputs from users, use conditional statements (`if-else`), and solve small everyday problems using Python.

2. Tasks and Programs Included

In this laboratory work, I created a few small Python scripts and saved them in my GitHub repository:

- **`Zodiac_Calculator.py`**: A program that asks the user for their birth month and day, checks the dates, and tells them their zodiac sign.
- **`BMI_hesablama.txt`**: A text file containing the code for calculating Body Mass Index (BMI). It takes the user's weight and height, calculates the index, and shows the health status.
- **`find_birthday.txt`**: A small script/note file used to practice date-related calculations.

3. How the Programs Work

Zodiac Calculator

This program uses `input()` to get the month and day from the user. Then, it uses `if-elif-else` conditions to match the date range and print the correct zodiac sign.

BMI Calculator

The program uses the standard formula to calculate BMI:

BMI=height2weight

It helps to see if a person is underweight, normal weight, or overweight based on the result.

4. Conclusion

During this laboratory work, I improved my skills in writing basic Python code. I practiced working with variables, user input, and math operations. All the tasks were successfully completed and uploaded to my GitHub repository.
